Abstract. Salt marshes are highly productive environments and economic importance, however, little attention is given to insects in this ecosystem, and its entomofauna unknown in Brazil. Thus, it is the first record for lepidopteran Southern Brazilian coastal marshes ($32^{\circ}01'S$; $052^{\circ}06'W$).

Keywords: Butterflies; estuary; moths.

Primeiro Registro de Lepidoptera em Marisma no Sul do Brasil

Resumo. Marismas são ambientes de grande produtividade e importância econômica, no entanto, pouca atenção é dada aos insetos neste ecossistema, sendo sua entomofauna desconhecida no Brasil. Assim, faz-se o primeiro registro de lepidópteros para as marismas do sul do Brasil ($32^{\circ}01'S$; $052^{\circ}06'W$).

Palavras-chave: Borboletas; estuário; mariposas.

The Order Lepidoptera has 150,000 species approximately, which 20,000 are butterflies (MIELKE & CASAGRANDE 1997). In the Neotropics there are nearly 38,000 species of moths and 8,000 of butterflies (HEPPNER 1991); and in Brazil there are about 25,000 species of moths and 3,300 butterflies (BROWN 1996).

In Brazil, data about the occurrence and distribution of Lepidoptera are scarce for many ecosystems, mainly in coastal areas. This lack of information makes difficult the evaluation and monitoring of priority areas for conservation (BALMER 2002), once this group has a huge insect-plant interaction, being potential biological indicators of health status of natural plant communities (MOTTA 1993).

Currently, several ecological essays about life cycle of aquatic animals in estuaries have been developed for dealing with high fertility areas; though, poor attention has been given to the insects in ecological reviews of coastal habitat (ADAM 1990). Moreover, with rising habitat destruction, it becomes increasingly important to conduct researches on biological diversity and ecosystems (WILSON 2000).

Salt marshes are among the wetlands of international importance in the context of conservation (SÃO PAULO 1997) and they are spread over almost the entire Brazilian coast (COSTA & DAVY 1992). The largest expanses of salt marshes in Brazil are found in the states of Santa Catarina (SORIANO-SIERRA 1990; PANITZ 1992) and Rio Grande do Sul (COSTA *et al.* 1997), where 95% of salt marsh area in the state lies in the extreme south, bordering the municipalities of Rio Grande and São José do Norte (COSTA & DAVY 1992).

Although insects are abundant throughout the salt marsh (COSTA 1998), data on interactions between insects and plants in the Brazilian coastal marshes are nonexistent. Therefore, this essay has the purpose of making the first record of Lepidoptera in a

Brazilian salt marsh.

Collections were made in the Ilha da Pôlvora ($32^{\circ}01'S$; $052^{\circ}06'W$) (Figure 1) which lies in Lagoa dos Patos estuary. It has an area of 45 ha, almost entirely covered by salt marshes.

The meteorological data were provided by Estação Meteorológica da Praticagem da Barra do Rio Grande ($32^{\circ}08,2'S$; $052^{\circ}06,2'W$).

The salt marshes are colonized by *Spartina alterniflora* (Loisel) in the frequent (frequently) flooded part, with the largest extent of the marshes dominated by *Spartina densiflora* (Brong) and *Scirpus maritimus* (Lam) (SEELIGER *et al.* 2004). The higher marshes are rarely flooded and receive the coverage of the bush *Myrsine parvifolia* (A. DC), known as *capororoca*. The woods of *capororoca* are mixed plant communities (i.e. with herbaceous plants, climbing plants and bushes). These amphibian trees may reach between 2-3 m tall, even though, they lack a dense canopy, which allows the formation of a significant herbal extract (SEELIGER *et al.* 2004).

The specimens were captured with an entomological net to rest beneath the woods of *capororoca*, taken to the laboratory, mounted and identified with the aid of expert guides (CANNALS 2003).

Agraulis vanillae incarnata (N. Riley), *Papilio cresphontes* (Cramer); *Eurema deva* (Doubleday) were collected at noon, on i/18/2010, under the following weather conditions: air relative humidity: 64%; precipitation: 0; average temperature: 28.6°C; wind: 22 km/h and North.

The caterpillar *Megalopyge urens* (Berg) was collected grazing on the leaves of *M. parvifolia* at 2:20 pm, on ii/08/2010, with

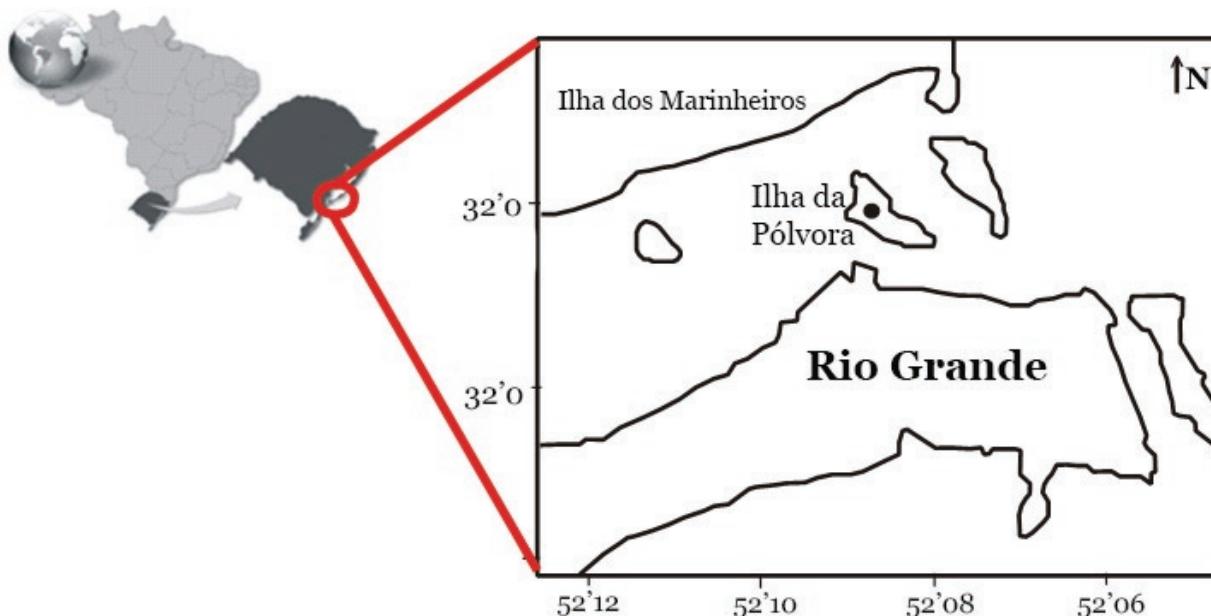

Figure 1. Study area – Ilha da Pólvora - Estuary of Lagoa dos Patos (Source: Laboratory of Decapod Crustaceans – Sector Entomology).

the environmental parameters: air relative humidity: 82%; precipitation: 0; average temperature: 27.3°C; wind: 19 km/h and west-southwest.
